## **ABSTRACT**

This work describes the data structures and procedures developed as a C++ implementation of the Incremental algorithm to calculate a triangulation called Delaunay triangulation, which is often used in several scientific applications as, for example, in the modeling of terrain surfaces. The implementation includes functions that perform computational geometry tasks on a set of points used as input and then generates a set of triangles as output.

# DESCRIÇÃO DE UMA IMPLEMENTAÇÃO EM C++ DO ALGORITMO INCREMENTAL PARA GERAR A TRIANGULAÇÃO DE DELAUNAY

## RESUMO

Este trabalho descreve as estruturas de dados e os procedimentos desenvolvidos como uma implementação em C++ do algoritmo Incremental para calcular uma triangulação chamada triangulação de Delaunay, a qual é muito utilizada em diversas aplicações científicas como, por exemplo, na modelagem de superfícies de terreno. A implementação inclui funções que executam tarefas de geometria computacional em um conjunto de pontos utilizados como entrada e gera um conjunto de triângulos como saída.

## 1 INTRODUCTION

Triangulations are structures generally comprised of several adjacent triangles of different sizes and shapes which are usually generated from a set of points distributed over space, where each point can be defined by a triple  $(x, y, z)$  with  $x$  and  $y$  as the coordinates on the horizontal plane and  $z$  as a particular value associated to the point  $(x, y)$ .

These structures have relevant and useful applications in many areas of natural sciences since digital elevation models are efficiently represented by triangulations (PETRIE; KENNIE, 1987; JONES et al., 1990; BERG et al., 2008) where the density of information can vary from region to region, thus avoiding data redundancy and producing a model that better adapts to the irregularities of the terrain.

The present work describes all the data structures and procedures developed as a C++ implementation of the Incremental algorithm to generate a particular triangulation called Delaunay triangulation.

## 2 DELAUNAY TRIANGULATION

A triangulation calculated from a set of points in the plane is defined as a subdivision of the plane such that any three points of the set are connected by edges to form the vertices of a triangle and all the edges of the triangulation do not intersect each other at points different from the vertices. Many distinct triangulations can be calculated from the same set of points and one particular triangulation is called the Delaunay triangulation (BERG et al., 2008), which avoids the generation of skinny triangles.

The main property of the Delaunay triangulation is that each triangle defines a circle through its three vertices that does not contain any other point of the set in its interior, so that this property is considered as a criteria for calculating the triangulation (TSAI, 1993). As a consequence of this property, the Delaunay triangulation presents more equiangular triangles and the minimum angle among all the triangles is maximized. Figure 2.1 shows a Delaunay triangulation together with the Delaunay criteria for a circle defined by the three vertices of a triangle.

Figure 2.1 - Delaunay triangulation criteria  
SOURCE: adapted from Jones et al. (1990)

The Delaunay triangulation can be generated by several different algorithms found in the literature, each one with a specific approach. Some of these algorithms are: Bowyer-Watson (BOWYER, 1981; WATSON, 1981), Incremental (GUIBAS et al., 1992; BERG et al., 2008), Divide-and-Conquer (CIGNONI et al., 1998), Fortune (FORTUNE, 1987) and Brute Force (O'ROURKE, 1998). This work describes the Incremental algorithm, which presents a time complexity of  $O(n \log n)$  (BERG et al., 2008) as an upper bound for the running time of the algorithm with an input dataset of size  $n$ . A C++ implementation of the algorithm is also given, with the data structures for points and triangles listed in annex A and all the global variables listed in annex B.

### 3 INCREMENTAL ALGORITHM

The first step of the Incremental algorithm is to define a triangle that contains the whole set of points to be triangulated located in its interior. In addition, each one of its vertices cannot be inside the circle that passes through any three points of the set, thus respecting the Delaunay criteria.

The coordinates of the vertices of this initial triangle are defined by a constant value  $K$  calculated from a point  $P$  that defines the width and height of an enclosing rectangle of the set of points as presented by Vomacka (2008) apud Zalik and Kolingerova (2003), where these authors consider the value of  $K$  as ten times greater than the larger rectangle dimension, either width or height.

This work considers the value of  $K$  calculated from a straight line with a slope equals to  $-1$ , where this line is translated up and to the right in relation to the point  $P$ , so that the intersections between the line and both the  $x$  and  $y$  axes determine the points  $(K, 0)$  and  $(0, K)$ , respectively. The initial enclosing triangle is then defined by the vertices  $(K, 0)$ ,  $(0, K)$  and  $(-K, -K)$  as illustrated in figure 3.1, where the black rectangle represents the enclosing rectangle of the set of points. The source code that defines the enclosing triangle is in annex C.

Figure 3.1 - Enclosing triangle of the set of points  
SOURCE: adapted from Vomacka (2008)

After defining the enclosing triangle, each point of the set is inserted one at a time into the current triangulation, then new edges are created and connected to the inserted point. These new edges are either connected to each one of the three vertices of the triangle that contains the point, if the point is located inside the triangle, or to

the vertices opposite to an edge shared by two triangles, if the point is exactly on an edge. The new edges of the triangles created are then considered as Delaunay edges, i.e., these edges respect the Delaunay criteria since the circle that passes through them does not include any other point in its interior.

However, the edges of each divided triangle need to be checked whether they are still Delaunay edges as a circle passing through both the points of one of the edges and also through the inserted point may include another point of the set inside it. In this case, the edge will be considered illegal. Figure 3.2 exhibits an example of illegal edge, where the circle that passes through the points of the edge  $p_i p_j$  and also through the point  $p_k$  includes the point  $p_l$  in its interior.

Figure 3.2 - Edge  $p_i p_j$  is illegal  
SOURCE: Berg et al. (2008)

Furthermore, when a triangle edge is considered illegal, it is modified by a rotation operation and its new points are the points opposite to the edge before the rotation, so that both the triangles that shared the edge before it is rotated are also changed into two new triangles. The rotated edge becomes a Delaunay edge since the interior angles of the new triangles is maximized as shown in figure 3.3, where two skinny triangles are changed after the rotation of the edge  $p_i p_j$  to  $p_k p_l$ .

An edge rotation can make the other two edges of the triangles that existed before the rotation become illegal. These edges also need to be checked if they are still Delaunay edges, otherwise they are rotated as well. This procedure of checking and rotating recursively repeats until no more edges are illegal. Therefore the triangulation is locally changed and triangles are modified around the inserted point.

Figure 3.3 - Rotating an edge maximizes interior angles of triangles  
 SOURCE: adapted from Berg et al. (2008)

In the programming level, for the previously mentioned modifications to be correctly applied to the triangulation, the triangle structure holds the information of each adjacent triangle as a pointer reference and these references change with each edge rotation in order to ensure that the adjacency relationships are maintained.

The Incremental algorithm uses a tree structure for the storage of the triangles as its nodes, where divided triangles and new triangles created are then connected in the tree by hierarchical links that indicate the triangles divisions. The new triangles are stored as children of the divided triangles, so that each triangle has three or two children depending on whether the inserted point is located inside a triangle or on an edge, respectively. At the end, Delaunay triangles are leaf nodes of the tree and the enclosing triangle, together with all its incident edges, is discarded. An example of how the triangles and the tree structure are modified after a point is inserted can be visualized in figure 3.4. The source code of the Incremental algorithm that calculates the Delaunay triangulation is in annex D with specific geometric and utility functions in annexes E and F, respectively.

Figure 3.4 - Tree structure reflects triangles divisions  
 SOURCE: adapted from Berg et al. (2008)

## 4 CONCLUSIONS

The implementation in a programming language of the Incremental algorithm to generate the Delaunay triangulation is not a trivial problem. Despite being comprised of simple recursive procedures, there are many details related to the information that is stored in the data structures and also to particular tasks of computational geometry that must be solved for the algorithm to work properly.

This work presented the source code of the Incremental algorithm written in the C++ programming language with data structures and procedures developed as a set of several functions that can be used in a computational geometry library as an alternative implementation to generate the Delaunay triangulation.
